Review articles & Guidelines

The PiCCO Technology provides a dynamic, minimally invasive measurement of cardiac output and its determinants (preload, afterload, contractility) as well as the quantification of pulmonary edema for a targeted treatment. It is a clinically proven tool for hemodynamic assessment and management in a broad range of critically ill patients. With its unique combination of intermittent transpulmonary thermodilution and continuous pulse contour analysis, the PiCCO Technology provides a complete picture of the hemodynamic situation. The basic principle of PiCCO has been explained in several review articles:

**Review articles**

**Guidelines**

Cost effectiveness

Several publications have reported an improved patient outcome when advanced hemodynamic variables are used to set up a goal directed treatment algorithm. In these studies, a reduction in complication rates has been reported and the subsequent treatment costs were reduced. While the incorporation of advanced hemodynamic monitoring is associated with an (initial) investment, the cost-reduction due to the decrease in complications is always higher than the investment.

Validation of PiCCO parameters

Accuracy of PiCCO thermodilution cardiac output compared to the pulmonary artery catheter

The two methods have comparable accuracy, however the PiCCO thermodilution method is less user-dependent and gives more stable measurements.

Accuracy of PiCCO pulse contour cardiac output compared to the pulmonary artery catheter

Several validation studies of the PiCCO pulse contour cardiac output versus pulmonary artery thermodilution have been published, within the early days of introduction of PiCCO in the market.

Accuracy of the lung water measurement (EVLW/ELWI) by PiCCO

Evidence shows that measurement of lung water with PiCCO for quantification of pulmonary edema is accurate and correlates strongly with the ‘gold standard’ gravimetric method.

Pediatrics

**General intensive care**

Two femoral PICCO catheters can be used in pediatrics (PV2013L07, 3F, 7cm and PV2014L08, 4F, 8cm). The decision about which kind of patient (age, weight) these catheters are used for, should be made by the treating physician. Recommendations on the body weight can be derived from publications e.g. Cecchetti et al. (Min Anest 2013), used a 3F catheter in a patient with body weight less than 10kg and 4F catheters in pediatric patients with at least 10kg body weight. In other publications, (e.g. Lemson et al., Crital Care 2010; Szekely et al., Ped Card 2010; Gil Anton et al., An Ped 2009; Egan et al, Intensive Care Med 2005; Cecchetti et al., Min Anest 2003) the youngest patients were aged 2 months with a body weight of 3 kg. A review on PICCO in pediatrics was published by Proulx et al (Pediatr Crit Care Med 2011).

Clinical & medical questions
Influence on PiCCO measurements in special clinical situations and therapies

Clinical situations

**Aortic aneurysm**

In patients with a known aortic aneurysm, if a femoral arterial catheter is used, the GEDI will be overestimated due to the volume of the aneurysm itself. In these cases, a brachial or axillary PICCO catheter is recommended.

**Valvulopathies, cardiac valve insufficiencies**

Valve insufficiency, especially aortic valve insufficiency, may cause regurgitation of the thermodilution injectate and prolong the transit time of the indicator; or interfere with the thermodilution curve. However, when a sufficient thermodilution curve is detected, the calculation of the cardiac output is considered correct. In mitral valve insufficiency, the accuracy of the PiCCO cardiac output measurement has been confirmed.

**Aortic stenosis**

In aortic stenosis, arterial thermodilution accurately reflects cardiac output. The arterial pressure curve may have reduced systolic and elevated diastolic pressures. However, the area under the arterial curve still reflects stroke volume. In severe aortic stenosis, recalibration of the pulse contour (with thermodilution) substantially improves reliability.

**Kinetic therapy (e.g. prone positioning)**

Research shows that the EVLW can be used to demonstrate the positive effect of laying the patient in a prone position. It has also been shown that the calibrated PiCCO is more accurate than non-calibrated systems.

Hypothermia

There is no influence on the thermodilution measurements as long as the patient's temperature is stable. Cooled injectate should be used.

- Demirgan S, Erkalp K, Sevdi MS, et al.
  Cardiac condition during cooling and rewarming periods of therapeutic hypothermia after cardiopulmonary resuscitation.

  The precision of PICCO® measurements in hypothermic post-cardiac arrest patients.
  Anaesthesia. 2012;67(3):236-243

Vasoconstrictor and/or inotrope therapy

All parameters are correctly calculated. In case of significant changes in catecholamines or volume therapy, recalibration of the pulse contour analysis is recommended.

  Effect of norepinephrine dosage and calibration frequency on accuracy of pulse contour-derived cardiac output.

- Hamzaoui O, Monnet X, Richard C, Osman D, Chemla D, Teboul JL.
  Effects of changes in vascular tone on the agreement between pulse contour and transpulmonary thermodilution cardiac output measurements within an up to 6-hour calibration-free period.

Effect of pleural effusion on ELWI

Pleural fluid does not affect the ELWI measurement. The capillary surface of the lung parenchyma that is in contact with the pleural fluid is very small in comparison to the pulmonary capillary network. Temperature loss to pleural fluid is also negligible.

- Deeren D, Dits H, Daelemans R, Malbrain ML.
  Effect of pleural fluid on the measurement of extravascular lung water by single transpulmonary thermodilution.

Effect of pulmonary embolism on ELWI

In pulmonary embolism, due to an obstruction in the pulmonary vasculature, EVLW is underestimated. Despite this, in this case the cardiac output and the global end-diastolic volume (GEDV) are still measured correctly.

- Schreiber T, Hüter L, Schwarzkopf K, et al.
  Lung perfusion affects preload assessment and lung water calculation with the transpulmonary double indicator method.

Therapies
**Intra-aortic Balloon Pump (IABP)**

The thermodilution measurement with PiCCO is not influenced by the IABP, but the pulse contour analysis is usually unable to provide valid continuous cardiac output and related parameters.

  *Accuracy and precision of transcardiopulmonary thermodilution in patients with cardiogenic shock.*  

  *The impact of intra-aortic balloon pumping on cardiac output determination by pulmonary arterial and transpulmonary thermodilution in pigs.*  
  J of Cardiovasc and Vasc Anesth. 2006;20(3):320-324

**Extracorporeal membrane oxygenation (ECMO), extracorporeal lung assist (ECLA)**

In an observational study in patients with veno-venous extra-corpooreal membrane oxygenation (ECMO) the PiCCO thermodilution measurement results for cardiac index were not significantly affected by the ECMO, providing accurate calibration of pulse contour analysis and reliable results for all continuous readings. In contrast, the results for global end-diastolic index (GEDI) and extravascular lung water index (ELWI) were significantly increased during the running vv-ECMO. Effects of a veno-arterial ECMO have not be investigated yet.

  *Assessment of left ventricular cardiac output by arterial thermodilution technique via a left atrial catheter in a patient on a right ventricular assist device.*  
  Perfusion. 2004;19(1):73-75

**Continuous renal replacement therapy (CRRT), hemofiltration, dialysis**

PICCO measurement results are accurate when the following criteria are fulfilled:

- PiCCO thermodilution measurements should not be taken directly after the CRRT is switched on or off
- A stable blood temperature baseline needs to be achieved before performing PiCCO measurements
- The CRRT catheter out- and inflow should not lie in the PiCCO indicator passage track

CLINICAL INDICATIONS

Effect of lung resection on ELWI

Lung resection procedures (lobectomy, bilobectomy, pneumectomy) theoretically reduce the pulmonary blood volume (PBV) and may lead to an underestimation of the extravascular lung water (EVLW). To evaluate this theoretical assumption, a double indicator dilution technique is required to determine PBV before and after lung resection. Clinical studies using this approach show that:

- The amount of extracted lung tissue and pulmonary blood volume do not correlate
- Clear correction factors for PBV calculation cannot be determined
- An initial effect on PBV is widely physiologically compensated, two days post-operatively at the latest

Thus, it is not recommended to correct the measured values for PBV and EVLW with fixed calculation factors. Clinical evidence is not available for this action. Such corrections may lead to unexpected and unpredictable errors in the calculation of EVLW in patients after lung resection.

Magnetic resonance imaging (MRI)

The effect of MRI on the PiCCO catheter has been investigated as observational study with survey analysis and in model experiments and published as congress poster abstracts. These investigations do not report any negative effects on the functionality of the PiCCO Catheter during MRI. However, there are currently no systematic tests for all available MRI systems under various measurement conditions. Therefore PULSION cannot confirm the compatibility of the PiCCO catheter with MRI systems and must recommend the removal of the PiCCO catheter before MRI. It is the treating physician’s full responsibility for the decision to leave the PiCCO Catheter in the patient during the MRI.

- Greco F, Vendrell JF, Deras P, Boullaran A, Perrigault PF. [The Pulsiocath catheter and magnetic resonance imaging.] Ann Fr Anesth Reanim 2011;30(9):697

Passive leg raising (PLR)

The PiCCO has been used in several investigations to show if a patient is volume responsive using passive leg raising.

Clinical significance of PiCCO parameters

Global end-diastolic volume index (GEDI) as an indicator of cardiac preload

Strictly defined, cardiac preload is the myocardial fibre stretch at the end of ventricular diastole. A parameter that accurately reflects preload in clinical practice is not yet available. However, studies have demonstrated that GEDI (or ITBI) is a reproducible and sensitive parameter and a good approximation of preload.

Fluid responsiveness by stroke volume variation (SVV) and pulse pressure variation (PPV)

The following requirements have to be fulfilled:

- Fully controlled mechanical ventilation with a tidal volume ≥ 8 ml/kg PBW (predicted body weight)
- Sinus rhythm
- Pressure curves free of artifacts

Validity and clinical relevance of the PiCCO Technology contractility parameters

The PiCCO Technology offers several contractility related parameters like the intermittent cardiac function index (CFI) and global ejection fraction (GEF) as well as the continuous left ventricular contractility (dPmx). The cardiac power index (CPO/CPI) can be considered a contractility parameter, even though it is usually classified as an organ function (cardiac) parameter.

Cardiac function index (CFI)

Left ventricular contractility (dPmx)

Cardiac power (CPO/CPI)

The cardiac power output/index (CPO/CPI) has been investigated in the past in patients with heart failure. It has been found that cardiac power is a direct indicator of the overall cardiac function and is the strongest independent predictor of in-hospital mortality in patients with cardiogenic shock. CPI is established as one of the target parameters in the German-Austrian S3 Guideline on diagnosis, monitoring and treatment of cardiogenic shock patients (Werdan et al., Dtsch Arztebl Int 2012).

Accuracy of chest x-ray for measuring pulmonary oedema

Research confirms that presently, it is not possible to quantify the extent of pulmonary edema with a chest x-ray. The interpretation of a chest x-ray is complex since it is a density measurement and influenced by all compartments in the chest, like bones, muscles, vessels, blood, air, skin layers, tissue edema, pleural effusion and, amongst the others, also by the extravascular lung water.

  Crit Care. 2010;14(3):R105
Quantification of pulmonary edema by the measurement of extravascular lung water index (ELWI)

The PiCCO Technology offers direct and accurate bedside quantification of pulmonary edema by the measurement of extravascular lung water index (ELWI). This enables a sensitive and early detection of the development of pulmonary edema and thus an early therapeutic intervention before pulmonary edema can cause alveolar damage and other complications. It is also an early predictor of acute respiratory distress syndrome (ARDS) and enables an improved classification of origin and severity.

Outcome improvement in ARDS patients

ARDS patient management based on the PiCCO Technology parameter of ELWI resulted in shorter ventilation time, better oxygenation index and improved survival.

Pulmonary vascular permeability index (PVPI) for differential diagnosis of pulmonary edema origin

In case of diagnosed pulmonary edema (high ELWI), the parameter of pulmonary vascular permeability index (PVPI) enables a differential diagnosis of its origin. Based on clinical studies, a PVPI value of less than 3 most likely indicates cardiogenic pulmonary edema (left heart failure, fluid overload) whereas a PVPI value 3 or above indicates pulmonary edema most likely due to permeability damage (sepsis, ARDS).

CLINICAL INDICATIONS

Outcome studies

Hemodynamic monitoring itself is not able to improve outcome. However, when the hemodynamic variables are used in a clearly defined treatment algorithm to manage individualized goal-directed therapy, there is a high potential for an improvement in outcome. Several studies have already confirmed improved outcome when PiCCO parameters are used to apply therapy for hemodynamic optimization in critically ill patients.

PiCCO measurements from a standard short radial artery catheter is not possible

In critically ill patients the arterial pressure waveform at the radial site is affected by vascular tone (vasoconstriction and dilation) and compliance, making arterial blood pressure measurements inaccurate. Also, due to the distance involved, it is not possible to record the downstream temperature required for the thermodilution measurement.

How many thermodilution measurements are recommended?

It is recommended that three consecutive measurements, with less than 15% (+/-) variation compared to the mean value are performed within a 10 minute time frame.

Considerations in case of thermodilution injection into the femoral vein and the PiCCO catheter placed in the femoral artery

If both the central venous catheter and PiCCO arterial catheters are placed on the same side (e.g. right femoral groin), the injectate may be detected immediately through the vessel wall (cross talk phenomena) resulting in measurement errors. This is more common in pediatric patients.

Cross talk can be avoided if the PiCCO arterial catheter is either placed in the opposite femoral artery or in the brachial / axillary artery. If placed femoral, thermodilution measurement is possible. PiCCO preload value and global end-diastolic volume (GEDI) will be slightly higher than the actual volume. The PiCCO2 software version V3.1 (and later versions) a confirmation of where both the central venous and arterial catheters are placed is asked, to ensure accurate calculation of GEDI.

Thermodilution injection with a room temperature instead of a cold injectate

Evidence shows that the use of room temperature injectate may not be as accurate. Therefore, particularly in patients with elevated lung water, the use of cold injectate is recommended.

Frequency of thermodilution injections to recalibrate continuous cardiac output

In general, the PiCCO should be calibrated every 8 hours by thermodilution. However, individual patient needs vary greatly. In case of hemodynamic instability, the pulse contour will deviate from the thermodilution cardiac output. In such cases, frequent recalibration (via thermodilution) is recommended.

PiCCO practical help

Find out how to optimize PiCCO thermodilution measurements in your daily use. Containing comprehensive practical support, the PiCCO Trouble Shooting Guide assists clinicians and technicians when in need for handling information.
